The Royal Wolverhampton NHS Trust

Anterior Vaginal Repair (Bladder Repair) without the use of mesh

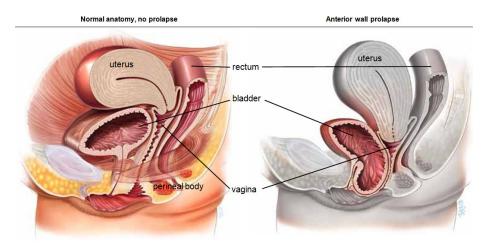

Gynaecology

Introduction

This leaflet has been designed to provide information for ladies who are considering having an anterior vaginal repair operation to treat their prolapse. It will cover the likely plan of care after the operation. It will also include the benefits, risks and alternatives of the procedure. Please feel free to ask a member of the team if there is anything for the procedure you do not understand.

What is an anterior vaginal wall prolapse?

A prolapse of the front (anterior) wall of the vagina is usually due to a weakness in the strong tissue layer (fascia) that divides the vagina from the bladder. This weakness may cause a feeling of fullness or dragging in the vagina or an uncomfortable bulge that extends beyond the vaginal opening. It may also cause difficulty passing urine with a slow or intermittent urine stream or symptoms of urinary urgency or frequency. Another name for an anterior wall prolapse is a cystocele.

What is an anterior vaginal repair?

An anterior repair, also known as an anterior colporrhaphy, is a surgical procedure to repair or reinforce the fascial support layer between the bladder and the vagina. About one in ten women who have had children require surgery for vaginal prolapse.

The prevention of infection is a major priority in all healthcare and everyone has a part to play.

- Please decontaminate your hands frequently for 20 seconds using soap and water or alcohol gel if available
- If you have symptoms of diarrhoea and/or vomiting, cough or other respiratory symptoms, a temperature or any loss of taste or smell please do not visit the hospital or any other care facility and seek advice from 111
- Keep the environment clean and tidy
- Let's work together to keep infections out of our hospitals and care homes.

Consent

We must seek your consent for any procedure or treatment beforehand. Your doctor will explain the risks, benefits, and alternatives where relevant before they ask for your consent. If you are unsure about any aspect of the procedure or treatment proposed, please do not hesitate to ask for more information.

What are the benefits of having an anterior repair performed?

The primary aim of the operation is to reduce the bulge within the vagina. There are benefits associated with this. You are likely to feel more comfortable. Intercourse may be more satisfactory. Your bladder may empty more effectively and urinary frequency and urgency may be reduced.

How is an anterior repair performed?

The operation is usually performed under general anaesthetic.

A general anaesthetic means you will be asleep during the entire procedure. Occasionally, it is done using a spinal anaesthetic which numbs you from the waist downwards following an injection in your back.

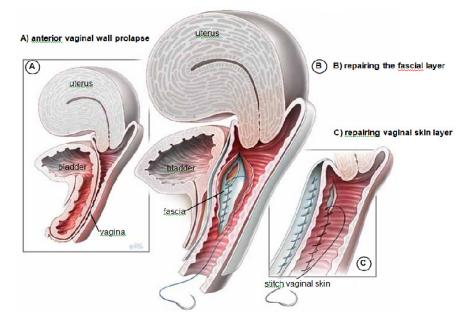

There are many ways to perform an anterior repair. Below is a general description of a common repair method.

An incision (cut) is made along the centre of the front wall of the vagina starting near the vaginal entrance and finishing near the top of the vagina. The vaginal skin is then separated from the underlying supportive fascial layer. The weakened fascia (tissue layer) is repaired using absorbable stitches, which will absorb over 4 weeks to 5 months depending on the type of stitch (suture) material used. Sometimes, excessive vaginal skin is removed and the vaginal skin is closed with absorbable sutures, these usually take 4 to 6 weeks to fully absorb. Reinforcement material in the form of biological (absorbable) graft may be used to repair the anterior vaginal wall. This is usually reserved for cases of repeat surgery or severe prolapse and your doctor will explain this to you if it is necessary.

A cystoscopy (camera into the bladder) may be performed to confirm that the appearance inside the bladder is normal and that no injury to the bladder or ureters (the tube from the kidneys to the bladder) has occurred during surgery.

A pack may be placed into the vagina and a catheter in to the bladder (to drain urine) at the end of surgery. If so, this is usually removed after 24 hours. The pack acts like a compression bandage to reduce vaginal bleeding and bruising following surgery.

Commonly, anterior vaginal repair surgery is combined with other surgery such as vaginal hysterectomy, posterior vaginal wall repair or incontinence surgery. These procedures are covered in detail in other leaflets and will be given to you as necessary.

How successful is anterior repair surgery?

Quoted success rates for anterior vaginal wall repair are 70 - 90%. There is a chance that the prolapse may come back in the future, or another part of the vagina may prolapse for which you may need further surgery.

What are the risks of anterior repair surgery?

With any surgery, there is always a small risk of complications.

General risks of surgery:

- Anaesthetic risk. This is very small unless you have specific medical conditions, such as a problem with your heart, or breathing. Smoking and being overweight also increase any risks
- **Bleeding.** There is a risk of bleeding with any operation. It is rare that we have to transfuse patients after their operation. Please let your doctor know if you are taking an anticlotting drug such as warfarin or aspirin. The risk of excessive bleeding during the operation is about 1 in 100 women
- Infection. There is a small risk of infection with any operation (about 10 cases in 100 operations).
 If it occurs, an infection can be a wound infection, vaginal infection or a urinary infection, and
 is usually treated with antibiotics. The risk of infection is reduced by routinely giving you a
 dose of antibiotic during your operation. Chest infection may also occur as a result of a general
 anaesthetic
- Deep Vein Thrombosis (DVT). This is a clot in the deep veins of the leg. Occasionally, this clot can travel to the lungs (pulmonary embolism) which can be very serious and in rare circumstances it can be fatal (less than 1 in 100 of those who get a clot). The risk increases with obesity, severe varicose veins, infection, immobility and other medical problems. The risk is significantly reduced by using special stockings and injections to thin the blood
- Bladder infections (cystitis) occur in about 6% of women after surgery and are more common if a catheter has been used. Symptoms include burning or stinging when passing urine, urinary frequency and sometimes, blood in the urine.

The following complications are more specifically related to anterior vaginal wall repair:

- **Constipation** is a common postoperative problem and your doctor may prescribe laxatives for this. Try to maintain a high fibre diet and drink plenty of fluids to help as well
- Pain with intercourse (dyspareunia). Some women develop pain or discomfort with intercourse. Whilst every effort is made to prevent this happening, it is sometimes unavoidable. Some women also find intercourse is more comfortable after their prolapse is repaired

- **Damage to the bladder or ureters** during surgery is an uncommon complication which can be repaired during surgery. Occasionally, the damage is not identified at the time of the surgery and may require a further operation to repair any damage
- Overactive bladder symptoms (urinary urgency and frequency) usually get better after the
 operation, but occasionally, can start or worsen after the operation. If you experience this, please
 make us aware so that we can treat you for it
- Incontinence. After a large anterior vaginal wall repair, some women develop stress urinary incontinence due to the unkinking of the urethra (the tube from the bladder). This can happen in about 10% of cases. Urodynamic studies (bladder tests) before surgery may help predict the chance of you having stress incontinence following an anterior repair. The test results may indicate the need to have a further procedure to try to prevent this being performed at the same time as the anterior repair or as a second procedure at a later date.

What happens if I do not have the operation?

Your problem may remain the same, get worse or improve over time. There is no sure way of predicting this.

Are there any alternatives to surgery?

Do nothing

If the prolapse (bulge) is not distressing, then treatment is not necessarily needed. If, however, the prolapse permanently protrudes through the opening to the vagina and is exposed to the air, it may become dried out and eventually ulcerate. Even if it is not causing symptoms in this situation, it is probably best to push it back with a ring pessary (see below) or have an operation to repair it.

Pelvic floor exercises (PFE)

The pelvic floor muscle runs from the coccyx at the back to the pubic bone at the front and off to the sides. This muscle supports your pelvic organs (uterus, vagina, bladder and rectum). Any muscle in the body needs exercises to keep it strong so that it functions properly. This is more important if that muscle has been damaged. PFE can strengthen the pelvic floor and therefore, give more support to the pelvic organs. These exercises may not get rid of the prolapse but they make you more comfortable. PFE are best taught by an expert who is usually a Continence Nurse Advisor or Women's Health Physiotherapist. The exercises have no risk and even if surgery is required at a later date, they will help your overall chance of being more comfortable.

Ring pessary

This is a soft plastic ring or device which is inserted into the vagina and pushes the prolapse back up. This usually gets rid of the dragging sensation and can improve urinary and bowel symptoms. It needs to be changed every 6 - 9 months, or earlier, if there is any bleeding or discharge, and can be very popular; we can show you an example in the clinic. Other pessaries may be used if the ring pessary is not suitable. Some couples feel that the pessary gets in the way during sexual intercourse, but many couples are not bothered by it. Shelf Pessary or Gellhorn - If you are not sexually active, this is a stronger pessary which can be inserted into the vagina and again needs changing every 4 - 6 months.

The choice about which treatment is best for you will be made together with your doctor. This will be based on the risks and benefits of the treatment and individual circumstances.

What should I expect before the operation?

Before admission for surgery, you will be asked to attend a pre-admission clinic to ensure that you are fit and well for your surgery. A nurse practitioner or a doctor will ask about your general health, past medical history and any medication that you are taking. Any necessary investigations will be arranged, such as blood tests, ECG (heart trace) and chest X-rays.

You will receive information about your admission, hospital stay, operation and pre and postoperative care. You will also be given the opportunity to ask any further questions that you may have. You are advised that you should not go on a long haul flight (more than four hours) in the six weeks prior to your surgery due to increased risk of clots in your legs.

Plan ahead - when you come out of hospital you are going to need extra help at home for the first two weeks. Make sure your family knows this.

If you smoke, try to stop completely. This will make your anaesthetic safer, reduce the risk of complications after operation, and speed up the recovery time. If you are unable to stop completely, even doing so for few days will be helpful.

Some medicines need to be stopped or altered before the operation. You should check with your GP and bring your list of medications with you when you come to the pre-admission clinic. If you are on a contraceptive pill, you should stop it at least four weeks before the operation and you should use another method of contraception.

What will happen on the day of my surgery?

On the day of your operation, you must have nothing to eat or drink for a specified time prior to your operation. You will be advised as to what time you need to stop eating and drinking.

Before your operation can take place, a doctor will see you to reconfirm your written consent, which will have already been obtained at a previous appointment.

You are requested to have a bath or shower before you come into hospital. Prior to your surgery, you will be asked to put on a theatre gown. You will be asked to remove all items of clothing including underwear, jewellery (except wedding rings) including all piercings, nail varnish, false nails, make up, contact lenses, hearing aids, dentures, wigs and any false limbs. You will be requested to wear a pair of elasticated stockings (TEDS). The stockings help to prevent clots (thrombosis) in your legs. You will need to keep these on until you are discharged from hospital. The nurses will advise you how long you will need to continue to wear the stockings following your discharge from hospital.

You will be escorted to the theatre by a member of the team. If a premedication (pre-med) has not been given, you may have the option of walking to the theatre, otherwise, a theatre trolley will be arranged to collect you from the ward.

You will be taken to the anaesthetic room where you will be asked a few questions. If you are having general anaesthesia, you will be given an injection into a vein usually in the back of your hand. Once you are asleep, you will be taken into theatre.

You will wake up in recovery area once your operation is finished. A nurse will then escort you back to your bed on the ward.

What will happen to me after the operation?

When you wake up from the anaesthetic, you will have a drip in your hand to give you fluids. The surgeon may place a vaginal pack (swabs inside the vagina) to stop any bleeding into the tissues. There will also be a tube in the bladder (catheter) to avoid urinary retention. The pack and catheter are usually removed within 48 hours of the surgery.

Will I have any pain following surgery?

Most people experience some pain or discomfort for the first few days and you will be offered pain relief to help ease it. Initially, you may need to have pain relief by injection to keep you comfortable. After this, you will have the choice of tablets or suppositories. You will be encouraged to take regular pain relief, as being pain-free will speed up your recovery. The anaesthetist will discuss pain relief with you before your operation.

Having an anaesthetic, being in pain, and having strong pain relief can sometimes make you feel nauseous or sick. This can be relieved by injections or tablets.

Many women get wind pains a few days after the operation, which can be uncomfortable and make the tummy look distended (swollen). This should not last long and can be relieved by medicines, eating and walking about.

You should avoid constipation and once you are eating and drinking again you can do this by:-

- Drinking plenty of water or juice
- Eating fruit and green vegetables, especially broccoli
- Eating plenty of roughage, such as bran or oats.

Will there be any bleeding?

• It is normal to get a creamy discharge for four to six weeks after surgery. This is due to the presence of stitches in the vagina; as the stitches absorb the discharge will gradually reduce. After the operation, you may have some slight vaginal bleeding and you may need to wear a sanitary pad. We advise that you do not use tampons for six weeks and avoid douching the vagina. Your vaginal loss should settle after about a week. (If you have any new pain, fresh bleeding or bad smelling discharge after you go home, you should contact your GP).

Will I have any stitches?

• You will have vaginal stitches, which are dissolvable. Threads may come away for up to three months, which is quite normal.

How will I cough?

• If you need to cough, your stitches will not come undone. You will be wearing a sanitary towel, and coughing will hurt less if you press on your pad firmly to give support between your legs. Any persistent cough following discharge should be treated promptly. Please see your GP as soon as possible.

When can I return to my usual routine?

Recovery is a time-consuming process, which can leave you feeling tired, emotionally low or tearful. The body needs time and help to build new cells and repair itself. You will need to take four to six weeks off work to recover. This also depends on the nature of your work. After anterior repair, most women stay in hospital for approximately two to three days, but it could be longer if necessary. Your date of discharge depends on the reasons for your operation, your general health and how smoothly things go after surgery. It is important to remember that everyone's experience is different. Recovery time varies from woman to woman and it is, therefore, best not to compare your own recovery with that of others on the ward.

When can I drive again?

You can drive as soon as you can operate the pedals and look over your shoulder without discomfort. Generally, this is after three weeks, but you must check this with your insurance company, as some of them insist that you should wait for six weeks.

When can I exercise again?

It is important to continue to exercise and walking is recommended. To help prevent DVT (Deep Vein Thrombosis), the same or the day after your operation, you will be encouraged to get out of bed and take short walks around the ward. This improves general wellbeing and reduces the risk of clots in the legs. You may be given a daily injection to keep your blood thin and reduce the risk of blood clots until you go home or longer in some cases, along with the anti-embolism stockings previously mentioned.

Once home, gradually increase the length of your walks, but remember to only walk the distance you can achieve comfortably. Cycling and swimming are equally good once discharge has settled.

You are encouraged to do pelvic floor exercises within one to two weeks of the operation.

Will I have a follow-up appointment?

You will usually have a follow-up appointment between six weeks and six months after the operation. This may be at the hospital (doctor or nurse), with your GP, by telephone or a postal survey. Sometimes, a follow-up is not required.

When can I have sex after the operation?

For many women, following recovery, this aspect of their life is improved because there is no longer any discomfort. We advise that you avoid penetrative intercourse for about six weeks. Take your time, feel comfortable, do not be rushed and for the first few times you might find a lubricating gel is helpful. You can buy this from the chemist. Talk to your partner about this, as you will need them to be extra gentle and understanding.

Is there any advice with regards to childbirth post-surgery?

If you are planning to have children after the procedure, a pregnancy may damage the repair and cause the prolapse to recur. To help prevent this, you may be advised to have a scheduled caesarean section rather than a vaginal birth.

What happens if I feel unwell after I go home?

You may expect some minor bleeding, especially some old, brownish blood for two weeks.

You should contact your GP or Ward D7 (01902 694034, 24 hours a day, 7 days a week) if you notice any of the following:

- Increased temperature
- Wound swelling
- Worsening pain
- Bad smelling discharge either from the wounds on your tummy or the front passage
- Blood in your urine or bowel motions
- Abdominal distension (swelling)
- Failure to open your bowel

Contact Information

Prior to your admission if you have any questions or worries you may contact your GP for advice or contact the urogynaecology nurse specialist on 01902 307999 Ext 85186, Monday to Friday, 8:30am – 4:30pm.

Useful support advice and literature is available:
